
Abstract

The Hybrid High Order (HHO) method is a powerful discretization method which has only been recently applied from to non linear computational mechanics.

The Hybrid High Order method divides the domain of interest in cells of arbitrary polyhedral shape, whose boundaries is called the skeleton, and introduces two kinds of degrees of freedom: the displacements in the cell and the displacements of the skeleton.

Most introductory materials to the HHO method is focus on the mathematical aspects of the methods. While those aspects are important, an approach based on physical considerations would help spreading this method to the computational mechanics and engineering communities.

This paper derives Hybrid High Order method from the classical Hu–Washizu functional.

Practical implementation of the method is discussed in depth using notations closed to the ones used in standard finite elements textbooks, highlighting the use of polyhedral cells and the use of approximation spaces based on polynomials of arbitrary orders.

From the point of view of numerical performances, the elimination of the cell degrees of freedom is mandatory to reduce the size of the stiffness matrix. The standard static condensation, is presented, as well as a novel strategy called "cell equilibrium". Advantages and disadvantages of both strategies are discussed.

The resolution of axi-symmetrical problems, which has seldom, if ever, been discussed in the literature, is then presented.

Numerical examples prove the robustness of the method with regards to volumetric locking...

1. Introduction

The origin of DG methods dates back to the pioneering work of [1], where an hyperbolic formulation is used to solve the neutron transport equation.

2. The model problem

2.1. The standard Hu–Washizu lagrangian

This paragraph introduces the standard Hu–Washizu three field principle. For the sake of simplicity, and without loss of generality, we consider the case of an hyperelastic material. Extensions to mechanical behaviours with internal state variables is treated in classical textbooks of computational mechanics. We will treat this extension in the Section 6 discussing the numerical implementation of the Hybrid High Order method and in Section 7 which provides several examples in plasticity.

2.1.1. Description of the mechanical problem and notations

Solid body. Let us consider a solid body whose reference configuration is denoted Ω . At a given time $t > 0$, the body is in the current configuration Ω_t .

Mechanical loading. The body is assumed to be submitted to a body force \mathbf{f}_v acting in Ω_t , a prescribed displacement \mathbf{u}_d on the Dirichlet boundary $\partial_d\Omega_t$, and a contact load \mathbf{t}_n on the Neumann boundary $\partial_n\Omega_t$.

Deformation. The transformation mapping Φ takes a point from the reference configuration Ω to the current configuration Ω_t such that

$$\Phi(\mathbf{X}) = \mathbf{x} = \mathbf{X} + \mathbf{u}(\mathbf{X}) \quad (1)$$

where \mathbf{X} , \mathbf{x} and \mathbf{u} denote respectively the position in the reference configuration Ω , the position in the current configuration Ω_t and the displacement.

Deformation gradient, gradient of the displacement. The deformation gradient \mathbf{F} is defined as:

$$\mathbf{F} = \nabla\Phi = \mathbf{I} + \mathbf{G} \quad (2)$$

where ∇ is the gradient operator in the reference configuration and $\mathbf{G} = \nabla\mathbf{u}$ denotes the gradient of the displacement.

Hyperelastic material. The body is assumed made of an hyperelastic material described by a free energy ψ_Ω which relates the deformation gradient \mathbf{F} and the first Piola-Kirchhoff stress tensor \mathbf{P} as follows:

$$\mathbf{P} = \frac{\partial\psi_\Omega}{\partial\mathbf{F}} \quad (3)$$

2.1.2. Primal problem and Principle of Virtual Works

The total Lagrangian L_Ω^{vw} of the body is defined as the stored energy minus the work of external loadings as follows:

$$L_\Omega^{vw} = \int_\Omega \psi_\Omega(\mathbf{F}(\mathbf{u})) - \int_\Omega \mathbf{f}_v \cdot \delta\mathbf{u} - \int_{\partial_N\Omega} \mathbf{t}_N \cdot \delta\mathbf{u}|_{\partial_N\Omega} \quad (4)$$

where the body forces \mathbf{f}_v and contact tractions \mathbf{t}_N in the reference configuration have been obtained from their counterparts \mathbf{f}_v and \mathbf{t}_n thanks to the Nanson formulae, i.e. $\mathbf{f}_v = \dots$ and $\mathbf{f}_v = \dots$. The displacement \mathbf{u} satisfying the mechanical equilibrium minimizes the Lagrangian L_Ω^{vw}

$$\mathbf{u} = \underset{\mathbf{u}^* \in U(\Omega)}{\operatorname{argmin}} L_\Omega^{vw}(\mathbf{u}^*) \quad (5)$$

where $U(\Omega)$ denotes the set of admissible displacements. Taking the first order variation of Lagrangian yields the principle of virtual work:

$$\frac{\partial L_\Omega^{vw}(\mathbf{u})}{\partial\mathbf{u}} = \int_\Omega \mathbf{P} : \nabla\delta\mathbf{u} = \int_\Omega \mathbf{f}_v \cdot \delta\mathbf{u} + \int_{\partial_N\Omega} \mathbf{t}_N \cdot \delta\mathbf{u}|_{\partial_N\Omega} \quad (6)$$

2.1.3. Mixed problem and Hu-Washizu functional

The Hu-Washizu Lagrangian generalizes the previous variational principle by considering that the gradient of the displacement \mathbf{G} and the first Piola-Kirchhoff \mathbf{P} stress are independent unknowns of the problem. The Hu-Washizu Lagrangian L^{HW} is then defined as follows:

$$L^{HW}(\mathbf{u}, \mathbf{G}, \mathbf{P}) = \int_\Omega \psi(\mathbf{I} + \mathbf{G}) + (\nabla\mathbf{u} - \mathbf{G}) : \mathbf{P} - \int_\Omega \mathbf{f}_v \cdot \mathbf{u} - \int_{\partial_N\Omega} \mathbf{t}_N \cdot \mathbf{u}|_{\partial_N\Omega} \quad (7)$$

and the solution \mathbf{u} , \mathbf{G} and \mathbf{P} minimize the Hu-Washizu Lagrangian L^{HW} :

$$(\mathbf{u}, \mathbf{G}, \mathbf{P}) = \underset{\substack{\mathbf{u}^* \in U(\Omega), \\ \mathbf{G}^*, \mathbf{P}^*}}{\operatorname{argmin}} L(\mathbf{u}^*, \mathbf{G}^*, \mathbf{P}^*) \quad (8)$$

The first order variation of the Hu-Washizu Lagrangian with respect to \mathbf{u} , \mathbf{G} , \mathbf{P} yields:

$$\frac{\delta L^{HW}}{\delta \mathbf{u}} = \int_{\Omega} \mathbf{P} \cdot \nabla \delta \mathbf{u} - \int_{\Omega} \mathbf{f}_V \cdot \delta \mathbf{u} - \int_{\partial_N \Omega} \mathbf{t}_N \cdot \delta \mathbf{u} \quad (9a)$$

$$\frac{\delta L^{HW}}{\delta \mathbf{P}} = \int_{\Omega} (\nabla \mathbf{u} - \mathbf{G}) \cdot \delta \mathbf{P} \quad (9b)$$

$$\frac{\delta L^{HW}}{\delta \mathbf{G}} = \int_{\Omega} \left(\frac{\partial \psi}{\partial \mathbf{G}} - \mathbf{P} \right) \cdot \delta \mathbf{G} \quad (9c)$$

Equation (9b) shows that \mathbf{G} is equal to $\nabla \mathbf{u}$ in a weak sense and Equation (9c) shows that the First Piola Kirchhoff stress is equal to the derivative of the free energy in a weak sense.

Some words about the importance of the Hu-Washizu principle. ...

3. Introduction to discontinuous methods through a Hu-Washizu formulation

Many numerical methods consider a partition of the body into elementary subsets called *cells*. For the equilibrium of the whole body to hold, each cell must be in equilibrium with its neighbors, which means that they have to interact and pass information from one another. Communication between two cells is ensured by knowledge of the displacement field at their shared boundary. For *conformal* methods to which belongs the Lagrange (*i.e.* the standard) Finite Element Method, the displacement over the whole body is continuous, which implies that the displacement at a cell boundary is directly equal to that of its neighbors, and a cell has a direct knowledge of the motion of its neighborhood. For so-called *non-conformal* methods, among which are *e.g.* Discontinuous Galerkin methods, Hybrid Discontinuous Galerkin methods and Hybrid High Order methods, the displacement continuity at a cell boundary is not explicitly enforced, such that one needs to introduce supplementary ingredients in the formulation to pass information from one cell to another. A straightforward way of doing so consists in introducing an interface between cells, that acts as a membrane pulling them together. One can readily feel that the stiffer the membrane, the closer the cells, and the closer to the *conformal* framework. This technique is the one at the foundation of Discontinuous Galerkin methods. By adding an intermediate structure in the membrane, called a *bone*, one defines the framework of Hybrid Discontinuous Galerkin methods and Hybrid High Order methods; the membrane is split into two parts, one at each side of the bone, and communication between cells transits through the bone, via the membrane. The term *hybrid* expresses the fact that both cells and bones carry information about the displacement field, hence introducing the *skeleton* of the body. In the following section, we show that one recovers the full mathematical framework proper to these non-conformal method, by writing the equilibrium of a cell and its interface with its neighborhood.

3.1. Partie 1

Element description. In the following, the cell T is assumed to be convex. It is split into a core part $K \subset T$ with boundary ∂K , and into an interface part $I \subset T$ with boundary $\partial I = \partial K \cup \partial T$, as shown in Figure 1. The interface I has some thickness $\ell > 0$ that is supposed to be small compared to h_T the diameter of T . From a geometrical standpoint, the core part of the element K is a homothety of T by some ratio inferior to 1.

Figure 1. schematic representation of the composite region

Element behaviour. The core of the element K is made out of the same material that composes Ω and behaves according to the free energy potential ψ_Ω . The interface I is made out of a linear elastic material of Young modulus $\beta(\ell/h_T)$ with a zero Poisson ratio and its behavior is defined by the free energy potential ψ_I such that

$$\psi_I = \frac{1}{2} \beta \frac{\ell}{h_T} \nabla \mathbf{u}_I : \nabla \mathbf{u}_I \quad (10)$$

where the dimensionless ratio ℓ/h_T balances the accumulated energy with the size of the domain T .

Element loading. The core K is subjected to the volumetric loading \mathbf{f}_V , and to the contact load applied by the interface I onto ∂K . By continuity of the traction force, the same opposite contact load acts on I . The interface I is also subjected to some contact load $\mathbf{t}_{\partial NT}$ acting on ∂T , that accounts for the action of the rest of the solid Ω onto T .

Element unknowns. Let note \mathbf{u}_K the displacement field, \mathbf{G}_K the displacement gradient field and \mathbf{P}_K the stress field in K . Similarly, let \mathbf{u}_I the displacement field, \mathbf{G}_I the displacement gradient field and \mathbf{P}_I the stress field in I . The displacement of the boundary ∂T is denoted $\mathbf{u}_{\partial T}$. By continuity of the displacement field between K and ∂T , the displacement \mathbf{u}_I verifies

$$\mathbf{u}_I|_{\partial K} = \mathbf{u}_K|_{\partial K} \quad (11a)$$

$$\mathbf{u}_I|_{\partial T} = \mathbf{u}_{\partial T} \quad (11b)$$

Hu-Washizu Lagrangian of the element. By combining both the Lagrangian of the core K and that of the interface I , one obtains the total Lagrangian L_T^{HW} over the element such that

$$L_T^{HW} = \int_K \psi_\Omega + (\nabla_X \mathbf{u}_K - \mathbf{G}_K) : \mathbf{P}_K + \int_I \psi_I + (\nabla_X \mathbf{u}_I - \mathbf{G}_I) : \mathbf{P}_I - \int_K \mathbf{f}_V \cdot \mathbf{u}_K - \int_{\partial NT} \mathbf{t}_{\partial NT} \cdot \mathbf{u}_{\partial T} \quad (12)$$

3.2. Hypotheses

The behavior and the kinematics having been described, let now make a number of assumptions on the expression of the fields of unknowns, exploiting the fact that the core is of negligible volume compared to the interface.

Displacement in the interface. Since the interface I is thin compared to the cell volume T , let linearize the displacement in the interface I with respect to \mathbf{n} , such that its gradient is homogeneous in I

$$\nabla \mathbf{u}_I = \frac{\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}}{\ell} \otimes \mathbf{n} \quad (13)$$

That is, the displacement of the interface I linearly bridges that of the boundary ∂T to that of the bulk K .

Stress in the interface. Furthermore, let assume that $\underline{\mathbf{P}}_I$ is constant along the direction \mathbf{n} in I . By continuity of the traction force across ∂K , the following equality holds true

$$(\underline{\mathbf{P}}_I - \underline{\mathbf{P}}_{K|\partial K}) \cdot \mathbf{n} = 0 \quad \text{in } I \quad (14)$$

3.3. Partie 2

Hu–Washizu avec hypothèses. Taking into accounts the assumptions made Section 3.2, the total Lagrangian of the system can be re-written (see Section 8 for details) in the following simplified form

$$\begin{aligned} J_T^{HW} = & \int_T \psi_\Omega + (\nabla \mathbf{u}_T - \underline{\mathbf{G}}_T) : \underline{\mathbf{P}}_T + \int_{\partial T} (\mathbf{u}_{\partial T} - \mathbf{u}_T|_{\partial T}) \cdot \underline{\mathbf{P}}_T|_{\partial T} \cdot \mathbf{n} + \int_{\partial T} \frac{\beta}{2h_T} \|\mathbf{u}_{\partial T} - \mathbf{u}_T|_{\partial T}\|^2 \\ & - \int_T \mathbf{f}_V \cdot \mathbf{u}_T - \int_{\partial_{NT}} \mathbf{t}_{\partial_{NT}} \cdot \mathbf{u}_{\partial T} \end{aligned} \quad (15)$$

where we have made the width of the interface $\ell \rightarrow 0$, such that the core part K now identifies as T .

hybridization of the primal unknown. The displacement is discontinuous across ∂T by considering the vanishing interface, that allows for the core part T to move away from the boundary ∂T , thus introducing a possible displacement jump on ∂T . This assumption relates to the concept of hybridization of the displacement unknown, which is at the foundation of Hybrid Discontinuous Galerkin methods. The displacement of the element T hence depends on the pair $(\mathbf{u}_T, \mathbf{u}_{\partial T})$, where the trace of the core unknown $\mathbf{u}_T|_{\partial T}$ coexists with $\mathbf{u}_{\partial T}$ on ∂T .

Discontinuous Galerkin. By replacing $\mathbf{u}_{\partial T}$ by $\mathbf{u}_{T'}|_{\partial T}$ for any neighbouring cell T' to T amounts to describe the framework for Discontinuous Galerkin methods, where only the core unknown \mathbf{u}_T is considered, and the displacement jump on ∂T depends on the trace of neighbouring cells displacement, instead of that only defined on the boundary.

Conformal Galerkin formulation. By enforcing continuity of the displacement across ∂T such that $\mathbf{u}_T|_{\partial T} = \mathbf{u}_{\partial T}$, one recovers the usual expression over

The displacement is discontinuous across ∂T by considering the vanishing interface, that allows for the core part T to move away from the boundary ∂T , thus introducing a possible displacement jump on ∂T . This assumption relates to the concept of hybridization of the displacement unknown, which is at the foundation of Hybrid Discontinuous Galerkin methods. The displacement of the element T hence depends on the pair $(\mathbf{u}_T, \mathbf{u}_{\partial T})$, where the trace of the core unknown $\mathbf{u}_T|_{\partial T}$ coexists with $\mathbf{u}_{\partial T}$ on ∂T .

Derivative. La fonctionnelle (15) définit le problème mixte sous forme faible, et revient à résoudre les problèmes couplés suivants

$$\frac{\partial J_T^{HW}}{\partial \mathbf{u}_T} \delta \mathbf{u}_T = \int_T \underline{\mathbf{P}}_T : \nabla \delta \mathbf{u}_T - \int_T \mathbf{f}_V \cdot \delta \mathbf{u}_T - \int_{\partial T} \boldsymbol{\theta}_{\partial T} \cdot \delta \mathbf{u}_T|_{\partial T} \quad \forall \delta \mathbf{u}_T \in U_0(T) \quad (16a)$$

$$\frac{\partial J_T^{HW}}{\partial \mathbf{u}_{\partial T}} \delta \mathbf{u}_{\partial T} = \int_{\partial_{NT}} (\boldsymbol{\theta}_{\partial T} - \mathbf{t}_{\partial_{NT}}) \cdot \delta \mathbf{u}_{\partial T} \quad \forall \delta \mathbf{u}_{\partial T} \in V_0(\partial T) \quad (16b)$$

$$\frac{\partial J_T^{HW}}{\partial \underline{\mathbf{G}}_T} \delta \underline{\mathbf{G}}_T = \int_T \left(\frac{\partial \psi_\Omega}{\partial \underline{\mathbf{G}}_T} - \underline{\mathbf{P}}_T \right) : \delta \underline{\mathbf{G}}_T \quad \forall \delta \underline{\mathbf{G}}_T \in G(T) \quad (16c)$$

$$\frac{\partial J_T^{HW}}{\partial \underline{\mathbf{P}}_T} \delta \underline{\mathbf{P}}_T = \int_T (\nabla \mathbf{u}_T - \underline{\mathbf{G}}_T) : \delta \underline{\mathbf{P}}_T + \int_{\partial T} (\mathbf{u}_{\partial T} - \mathbf{u}_T|_{\partial T}) \cdot \delta \underline{\mathbf{P}}_T|_{\partial T} \cdot \mathbf{n} \quad \forall \delta \underline{\mathbf{P}}_T \in S(T) \quad (16d)$$

where we introduced the *reconstructed traction force* $\boldsymbol{\theta}_{\partial T} = \underline{\mathbf{P}}_T|_{\partial T} \cdot \mathbf{n} + (\beta/h_T)(\mathbf{u}_{\partial T} - \mathbf{u}_T|_{\partial T})$. In particular, (16a) is the expression of the principle of virtual works in T , where the *reconstructed traction force* $\boldsymbol{\theta}_{\partial T}$ replaces the usual expression $\underline{\mathbf{P}}_T \cdot \mathbf{n}$ in the external contribution. (16b) denotes a supplementary equation to the usual continuous problem as described in (9), to account for the continuity of the flux $\boldsymbol{\theta}_{\partial T}$ across the cell boundary. (16c) accounts for the constitutive equation in a weak sense, and (16d) defines the equation of an enhanced gradient field, that does not reduce to the projection of $\nabla \mathbf{u}_T$ as in (9c), since it is enriched by a boundary component that depends on the displacement jump, which is at the origin of the robustness of non-conformal methods to volumetric locking (see Section 8).

3.4. Problem in primal form

Reconstructed gradient. Since minimization of (16d) defines a linear problem with any displacement pair $(\mathbf{v}_T, \mathbf{v}_{\partial T})$, one can eliminate the equation from the system (16), which defines the so-called *reconstructed gradient* $\mathbf{G}_T(\mathbf{v}_T, \mathbf{v}_{\partial T})$ associated with any displacement pair $(\mathbf{v}_T, \mathbf{v}_{\partial T})$ that solves

$$\int_T \mathbf{G}_T(\mathbf{v}_T, \mathbf{v}_{\partial T}) : \boldsymbol{\tau}_T = \int_T \nabla \mathbf{v}_T : \boldsymbol{\tau}_T + \int_{\partial T} (\mathbf{v}_{\partial T} - \mathbf{v}_T|_{\partial T}) \cdot \boldsymbol{\tau}_T|_{\partial T} \cdot \mathbf{n} \quad \forall \boldsymbol{\tau}_T \in S(T) \quad (17)$$

Stress tensor. Equation (16c) is also linear with the derivative of ψ_Ω with respect to \mathbf{G}_T , and one can eliminate it as well from (16), hence defining the stress tensor

$$\int_T \mathbf{P}_T : \boldsymbol{\chi}_T = \int_T \frac{\partial \psi_\Omega}{\partial \mathbf{G}_T} : \boldsymbol{\chi}_T \quad \forall \boldsymbol{\chi}_T \in G(T) \quad (18)$$

In particular, one notices that (18) holds in a strong sense if $S(T) \subset G(T)$.

Simplified form. Now that (16c) and (16d) have been eliminated from the system, one considers the simplified functional (19) instead of (15)

$$J_T^{VW} = \int_T \psi_\Omega + \int_{\partial T} \frac{\beta}{2h_T} \|\mathbf{u}_{\partial T} - \mathbf{u}_T|_{\partial T}\|^2 - \int_T \mathbf{f}_V \cdot \mathbf{u}_T - \int_{\partial_{NT}} \mathbf{t}_{\partial_{NT}} \cdot \mathbf{u}_{\partial T} \quad (19)$$

Principle of virtual works. The problem in primal form amounts to find the displacement pair $(\mathbf{u}_T, \mathbf{u}_{\partial T}) \in U(\bar{T})$ verifying $\mathbf{u}_{\partial T} = \mathbf{u}_D$ on $\partial_D T$, such that for all kinematically admissible displacements pairs $(\delta \mathbf{u}_T, \delta \mathbf{u}_{\partial T}) \in U_0(\bar{T})$, the functional (19) is minimal, *i.e.* such that

$$\delta J_{T,\text{int}}^{VW} - \delta J_{T,\text{ext}}^{VW} = 0 \quad (20)$$

with

$$\delta J_{T,\text{int}}^{VW} = \int_T \mathbf{P}_T(\mathbf{G}_T(\mathbf{u}_T, \mathbf{u}_{\partial T})) : \mathbf{G}_T(\delta \mathbf{u}_T, \delta \mathbf{u}_{\partial T}) + \int_{\partial T} (\beta/h_T) \mathbf{Z}_{\partial T}(\mathbf{u}_T, \mathbf{u}_{\partial T}) \cdot \mathbf{Z}_{\partial T}(\delta \mathbf{u}_T, \delta \mathbf{u}_{\partial T}) \quad (21a)$$

$$\delta J_{T,\text{ext}}^{VW} = \int_{\partial_{NT}} \mathbf{t}_{\partial_{NT}} \cdot \delta \mathbf{u}_{\partial T} + \int_T \mathbf{f}_V \cdot \delta \mathbf{u}_T \quad (21b)$$

where we introduced the jump function $\mathbf{Z}_{\partial T}$:

$$\mathbf{Z}_{\partial T}(\mathbf{v}_T, \mathbf{v}_{\partial T}) = \mathbf{v}_{\partial T} - \mathbf{v}_T|_{\partial T} \quad \forall (\mathbf{v}_T, \mathbf{v}_{\partial T}) \in U(\bar{T}) \quad (22)$$

In particular, one can readily see the resemblance of (21) with (6), where the so called *reconstructed gradient* $\mathbf{G}_T(\mathbf{u}_T, \mathbf{u}_{\partial T})$ plays the role of the usual displacement Lagrangian gradient $\nabla \mathbf{u}_T$, and where an additional *stabilization term* corresponding to a traction energy on the boundary has been added to account for the penalization of the displacement jump on ∂T through $\mathbf{Z}_{\partial T}$ (or, equivalently, to account for the infinitésimale interface that lays between the bulk domain and its boundary). Equations (19), (17) and (18) define the mechanical problem to solve at the cell level for Hybrid Discontinuous Galerkin methods, and (20) describes the weak form of these equations.

4. Discretization

Mesh. One defines the collection of all cells in the mesh as $\mathcal{T}(\Omega) = \{T_i \subset \Omega \mid 1 \leq i \leq N_T\}$, where N_T denotes the total number of cells.

Face. The boundary ∂T of each element is decomposed in faces, such that a face F is a subset of Ω , and either there are two cells T and T' such that $F = \partial T \cap \partial T'$ (F is then an interior face), or there is a single cell T such that $F = \partial T \cap \partial \Omega$ (F is then an exterior face).

Faces sets. For any element $T \in \mathcal{T}$, let $\mathcal{F}(T) = \{F \in \mathcal{F} \mid F \subset \partial T\}$ the set of faces composing the boundary of T . Let finally $\mathcal{F}(\Omega) = \{F_i \subset \Omega \mid 1 \leq i \leq N_F\}$ the skeleton of the mesh, collecting all element faces F_i in the mesh, where N_F denotes the number of faces.

Hybird mesh. The composition of both $\mathcal{T}(\Omega)$ and $\mathcal{F}(\Omega)$ forms the hybrid mesh $\bar{\mathcal{T}}(\Omega) = \{\mathcal{T}(\Omega), \mathcal{F}(\Omega)\}$.

Global unknown. Let the global unknown $(\mathbf{v}_T, \mathbf{v}_F)$ a displacement pair such that for each $T \in \mathcal{T}(\Omega)$, $\mathbf{v}_T = \mathbf{v}_T$ in T and for each $F \in \mathcal{F}(\Omega)$, $\mathbf{v}_F = \mathbf{v}_F$ on F , where $\mathbf{v}_T \in U(T)$ and $\mathbf{v}_F \in V(\partial T)$ denote a cell and a face displacement field respectively.

Global weak form. The weak form of the global mechanical problem of Ω reads : find the global displacement unknown pair $(\mathbf{u}_T, \mathbf{u}_F)$ verifying $\mathbf{u}_F|_{\partial_D \Omega} = \mathbf{u}_D$ on $\partial_D \Omega$ such that $\forall (\delta \mathbf{u}_T, \delta \mathbf{u}_F) \in U_0(\bar{\mathcal{T}})$

$$\delta J_{\mathcal{T}, \text{int}}^{VW} - \delta J_{\mathcal{T}, \text{ext}}^{HW} = 0 \quad (23)$$

with

$$\delta J_{\mathcal{T}, \text{int}}^{VW} = \sum_{T \in \mathcal{T}(\Omega)} \int_T \underline{\mathbf{P}}_T(\underline{\mathbf{G}}_T(\mathbf{u}_T, \mathbf{u}_{\partial T})) : \underline{\mathbf{G}}_T(\delta \mathbf{u}_T, \delta \mathbf{u}_{\partial T}) + \int_{\partial T} (\beta/h_T) \mathbf{Z}_{\partial T}(\mathbf{u}_T, \mathbf{u}_{\partial T}) \cdot \mathbf{Z}_{\partial T}(\delta \mathbf{u}_T, \delta \mathbf{u}_{\partial T}) \quad (24a)$$

$$\delta J_{\mathcal{T}, \text{ext}}^{HW} = \sum_{F \in \mathcal{F}_N(\Omega)} \int_F \mathbf{t}_N \cdot \delta \mathbf{u}_F + \sum_{T \in \mathcal{T}(\Omega)} \int_T \mathbf{f}_V \cdot \delta \mathbf{u}_T \quad (24b)$$

where for each element $T \in \mathcal{T}(\Omega)$, the boundary displacement field $\mathbf{v}_{\partial T}$ is such that $\mathbf{v}_{\partial T} = \mathbf{v}_F$ on F for every $F \in \mathcal{F}(T)$

Discrete functional space. A polynomial approximation of the global solution is then sought in a subspace of $U(\mathcal{T})$, and for each element $T \in \mathcal{T}(\Omega)$, we denote $U^h(T) \subset U(T)$ the approximation displacement space in the cell, and $V^h(\partial T) \subset V(\partial T)$ that on the boundary. Similarly, let $G^h(T) \subset G(T)$ the space used to build the discrete reconstructed gradient and $S^h(T) \subset S(T)$ that chosen for the discrete stress such that

$$\begin{aligned} U^h(T) &= P^l(T, \mathbb{R}^d) \\ V^h(\partial T) &= P^k(\partial T, \mathbb{R}^d) \\ G^h(T) &= P^k(T, \mathbb{R}^{d \times d}) \\ S^h(T) &= P^k(T, \mathbb{R}^{d \times d}) \end{aligned}$$

where the cell displacement polynomial order l might be chosen different from the face displacement order k such that $k - 1 \leq l \leq k + 1$. Accounting for the possible different polynomial order between the cell and faces, one can specify a discrete jump function in a natural way such that it delivers the displacement difference point-wise for any displacement pair $(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) \in U^h(\bar{T})$

$$\mathbf{Z}_{\partial T}^{HDG}(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) = \Pi_{\partial T}^k(\mathbf{v}_{\partial T}^k - \mathbf{v}_T^l|_{\partial T}) \quad (25)$$

where $U^h(\bar{T}) = U^h(T) \times V^h(\partial T)$ and $\Pi_{\partial T}^k$ denotes the orthogonal projector onto $V^h(\partial T)$. This straightforward discrete jump function is at the origin of Hybrid Discontinuous Galerkin methods, and grants a convergence of order k in the energy norm. A richer discrete jump function $\mathbf{Z}_{\partial T}^{HHO}$ providing a convergence of order $k + 1$ in the energy norm was introduced in [2], hence giving the Hybrid High Order method its name, such that

$$\mathbf{Z}_{\partial T}^{HHO}(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) = \Pi_{\partial T}^k(\mathbf{v}_{\partial T}^k - \mathbf{v}_T^l|_{\partial T} - ((I_T^{k+1} - \Pi_T^k)(\mathbf{w}_T^{k+1}))|_{\partial T}) \quad (26)$$

where Π_T^k is the projector onto $P^k(T, \mathbb{R}^d)$, I_T^{k+1} is the identity function in $D^h(T) = P^{k+1}(T, \mathbb{R}^d)$, and $\mathbf{w}_T^{k+1} \in D^h(T)$ denotes a higher order discrete displacement solving the following linear problem for any displacement pair $(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) \in U^h(\bar{T})$

$$\int_T \nabla \mathbf{w}_T^{k+1} : \nabla \mathbf{d}_T^{k+1} = \int_T \nabla \mathbf{v}_T^l : \nabla \mathbf{d}_T^{k+1} + \int_{\partial T} (\mathbf{v}_{\partial T}^k - \mathbf{v}_T^l) \cdot \nabla \mathbf{d}_T^{k+1} \cdot \mathbf{n} \quad \forall \mathbf{d}_T^{k+1} \in D^h(T) \quad (27a)$$

$$\int_T \mathbf{w}_T^{k+1} = \int_T \mathbf{v}_T^l \quad (27b)$$

Let $U^h(\mathcal{T}) = \prod_{T \in \mathcal{T}(\Omega)} U^h(T)$ the global discrete cell displacement space, $V^h(\mathcal{F}) = \prod_{F \in \mathcal{F}(\Omega)} V^h(F)$ the global discrete face displacement space, and $U^h(\bar{\mathcal{T}}) = U^h(\mathcal{T}) \times V^h(\mathcal{F})$ the global unknown approximation space. Let $U_0^h(\mathcal{T})$ and $V_0^h(\mathcal{F})$ the respective discrete mesh and skeleton virtual displacement spaces, and $U_0^h(\bar{\mathcal{T}}) = U_0^h(\mathcal{T}) \times V_0^h(\mathcal{F})$ the discrete virtual global displacement space.

The global mechanical problem in discrete weak form for the Hybrid High Order method finally writes : find the global displacement unknown pair $(\mathbf{u}_T^l, \mathbf{u}_F^k) \in U^h(\bar{\mathcal{T}})$ verifying $\mathbf{u}_F^k|_{\partial_D \Omega} = \mathbf{u}_D$ on $\partial_D \Omega$ such that $\forall (\delta \mathbf{u}_T^l, \delta \mathbf{u}_F^k) \in U_0^h(\bar{\mathcal{T}})$

$$\delta J_{\mathcal{T}, \text{int}}^{HHO} - \delta J_{\mathcal{T}, \text{ext}}^{HHO} = 0 \quad (28)$$

with

$$\delta J_{\mathcal{T}, \text{int}}^{HHO} = \sum_{T \in \mathcal{T}(\Omega)} \int_T \mathbf{p}_T^k(\mathbf{G}_T^k(\mathbf{u}_T^l, \mathbf{u}_{\partial T}^k)) : \mathbf{G}_T^k(\delta \mathbf{u}_T^l, \delta \mathbf{u}_{\partial T}^k) + \int_{\partial T} (\beta/h_T) \mathbf{Z}_{\partial T}^{HHO}(\mathbf{u}_T^l, \mathbf{u}_{\partial T}^k) \cdot \mathbf{Z}_{\partial T}^{HHO}(\delta \mathbf{u}_T^l, \delta \mathbf{u}_{\partial T}^k) \quad (29a)$$

$$\delta J_{\mathcal{T}, \text{ext}}^{HHO} = \sum_{F \in \mathcal{F}_N^e(\Omega)} \int_F \mathbf{t}_N \cdot \delta \mathbf{u}_F^k + \sum_{T \in \mathcal{T}(\Omega)} \int_T \mathbf{f}_V \cdot \delta \mathbf{u}_T^l \quad (29b)$$

with the discrete reconstructed gradient $\mathbf{G}_T^k(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) \in G^h(T)$ solving $\forall (\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) \in U^h(\bar{T})$

$$\int_T \mathbf{G}_T^k(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) : \boldsymbol{\tau}_T^k = \int_T \nabla \mathbf{v}_T^l : \boldsymbol{\tau}_T^k + \int_{\partial T} (\mathbf{v}_{\partial T}^k - \mathbf{v}_T^l|_{\partial T}) \cdot \boldsymbol{\tau}_T^k|_{\partial T} \cdot \mathbf{n} \quad \forall \boldsymbol{\tau}_T^k \in S^h(T) \quad (30)$$

5. A HHO method for the axi-symmetric framework

In the following section, we derive a Hybrid High order method for an axi-symmetric framework. The cartesian space is expressed in cylindrical coordinates and a point $\mathbf{x} \in \Omega$ has coordinates $\mathbf{x} = (r, z, \theta)$ where r denotes the radial component, z the ordinate one, and θ is the angular component describing a revolution around the axis $r = 0$. By cylindrical symmetry, the angular displacement u_θ is supposed to be zero, and both components u_r and u_z do not depend on the angular coordinate θ . Adopting notations introduced in Section 3, let T an open subset of $\Omega \subset \mathbb{R}^2$ in the (r, z) plane with cell displacement $\mathbf{u}_T \in U(T)$ and boundary displacement $\mathbf{u}_{\partial T} \in V(\partial T)$. The partial derivatives of \mathbf{u}_T with respect to the cylindrical coordinates are given by :

$$\forall i, j \in \{r, z\}, u_{Ti,j} = \frac{\partial u_{Ti}}{\partial j} \quad \text{and} \quad u_{T\theta,\theta} = \frac{u_{Tr}}{r} \quad (31)$$

In order to express a Hybrid High Order method in such a framework and owing to the assumptions on the displacement and its gradient, the definition of the reconstructed gradient (17) needs be modified accordingly, and the angular component $G_{T\theta\theta}$ does not define by the same equation as those in the other directions. In particular, for any displacement pair $(\mathbf{v}_T, \mathbf{v}_{\partial T}) \in U(T) \times V(\partial T)$, the component $G_{T\theta\theta}(\mathbf{v}_{Tr}, \mathbf{v}_{\partial Tr})$ solves

$$\int_T 2\pi r G_{T\theta\theta}(\mathbf{v}_{Tr}, \mathbf{v}_{\partial Tr}) \tau_{T\theta\theta} = \int_T 2\pi r \frac{u_{Tr}}{r} \tau_{T\theta\theta} = \int_T 2\pi u_{Tr} \tau_{T\theta\theta} \quad \forall \boldsymbol{\tau}_T \in S(T) \quad (32)$$

whereas in the radial and ordonal directions, i.e. $\forall i, j \in \{r, z\}$, the expression given in (17) is retrieved, and the component $G_{Tij}(\mathbf{v}_{Ti}, \mathbf{v}_{\partial Ti})$ solves :

$$\int_T 2\pi r G_{Tij}(\mathbf{v}_{Ti}, \mathbf{v}_{\partial Ti}) \tau_{Tij} = \int_T 2\pi r \frac{\partial u_{Ti}}{\partial j} \tau_{ij} - \int_{\partial T} 2\pi r (u_{\partial Ti} - u_{Ti}|_{\partial T}) \tau_{Tij}|_{\partial T} n_j \quad \forall \boldsymbol{\tau}_T \in S(T) \quad (33)$$

As for the reconstructed gradient, the higher order potential term needed to define the HHO jump function needs also be reconsidered such that $\forall \mathbf{d}_T^{k+1} \in D^h(T)$, the radial component w_{Tr}^{k+1} solves

$$\begin{aligned} \int_T 2\pi r \left(\sum_{i \in \{r, z\}} \frac{\partial w_{Tr}^{k+1}}{\partial i} \frac{\partial d_{Tr}^{k+1}}{\partial i} + \frac{w_{Tr}^{k+1}}{r} \frac{d_{Tr}^{k+1}}{r} \right) &= \int_T 2\pi r \left(\sum_{i \in \{r, z\}} \frac{\partial u_{Tr}}{\partial i} \frac{\partial d_{Tr}^{k+1}}{\partial i} + \frac{u_{Tr}}{r} \frac{d_{Tr}^{k+1}}{r} \right) \\ &+ \int_{\partial T} 2\pi r \sum_{i \in \{r, z\}} (u_{\partial Tr} - u_{Tr}|_{\partial T}) \frac{\partial d_{Tr}^{k+1}}{\partial i} |_{\partial T} n_i \end{aligned} \quad (34)$$

and the ordinate component w_{Tz}^{k+1} solves :

$$\int_T 2\pi r \sum_{i \in \{r,z\}} \frac{\partial w_{Tz}^{k+1}}{\partial i} \frac{\partial d_{Tz}^{k+1}}{\partial i} = \int_T 2\pi r \sum_{i \in \{r,z\}} \frac{\partial u_{Tz}}{\partial i} \frac{\partial d_{Tz}^{k+1}}{\partial i} - \int_{\partial T} 2\pi r \sum_{i \in \{r,z\}} (u_{\partial Tz} - u_{Tz}|_{\partial T}) \frac{\partial d_{Tz}^{k+1}}{\partial i} |_{\partial T} n_i \quad (35a)$$

$$\int_T 2\pi r w_{Tz}^{k+1} = \int_T 2\pi r u_{Tz} \quad (35b)$$

In particular, one notices that the mean value condition is not needed on the radial component of the higher order displacement since the left hand side of the system described by (34) depends directly on the displacement unknown and not only on its gradient as in (35).

Moreover, since in cylindrical coordinates, all integrals depend on the radial component r , there is a singularity at $r = 0$ for boundary integrals on faces located on the symmetry axis, and from a geometrical standpoint, these faces lose a dimension; a face that is not located on the symmetry axis behaves like a shell by revolution of the (r, z) plane, whereas one attached to the axis reduces to a beam that is only allowed to move and morph in the z direction. On a more algebraic note, the problem as such is ill-defined, since building the jump function involves inverting a mass matrix in $V^h(\partial T)$ to define the projector $\Pi_{\partial T}^k$. Therefore, a face on the axis is swelled by a small radius ϱ such that it becomes a cylinder with same dimensions as the others (see Figure 2)

Figure 2. schematic representation of the modeling of a face located on the symmetry axis

6. Implementation

Let Q_T a quadrature of T of order at least $2k$. In the following, the expression $\{\cdot\}$ denotes a real-valued vector, and the notation $[\cdot]$ a real-valued matrix. From an algebraic standpoint, (30) defines a linear problem consisting in inverting a mass matrix in $G^h(T)$ in order to obtain $[B_T]$ the discrete gradient operator acting on the pair $(\mathbf{v}_T^l, \mathbf{v}_T^k)$ at a quadrature point $\mathbf{x}_q \in Q_T$, such that the algebraic realization of (30) reads

$$\{\mathbf{G}_T^k(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k)\}(\mathbf{x}_q) = [B_T \quad B_{\partial T}](\mathbf{x}_q) \cdot \begin{Bmatrix} \mathbf{v}_T^l \\ \mathbf{v}_{\partial T}^k \end{Bmatrix} \quad \forall (\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) \in U^h(\bar{T}) \quad (36)$$

where we have decomposed the expression of the discrete gradient operator $[B_T]$ into a cell block B_T and a boundary block $B_{\partial T}$, to emphasize the dependence of the problem on both unknowns. Similarly, the algebraic realization of (26) amounts to compute the stabilization operator $[Z_T]$ such that

$$\{\mathbf{Z}_{\partial T}^{HHO}(\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k)\} = [Z_T \quad Z_{\partial T}] \cdot \begin{Bmatrix} \mathbf{v}_T^l \\ \mathbf{v}_{\partial T}^k \end{Bmatrix} \quad \forall (\mathbf{v}_T^l, \mathbf{v}_{\partial T}^k) \in U^h(\bar{T}) \quad (37)$$

Since (30) and (26) depend on the geometry of the element T only, one can compute the operators $[B_T]$ and $[Z_T]$ for each element once and for all in an offline pre-computation step by working in the reference configuration. Once

this offline step is performed, the algebraic form of the problem resembles closely to the standard finite element one, where the operator $[B_T]$ replaces the usual shape function gradient operator, and the stabilization operator $[Z_T]$ is incorporated in the expression of the tangent matrix and in that of internal forces.

In the following, let $(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})$ denote the displacement pair value at some pseudo time step m and some iteration n . The initial value of the displacement at time step $m = 0$ and iteration $n = 0$ is set to zero, and at a new pseudo time step $m + 1$, the displacement at the first iteration $n = 0$ takes the value of the displacement of the last iteration of the previous time step. In such a context, the internal forces vector $\{F_T^{int}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})\}$ writes

$$\begin{aligned} \{F_T^{int}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})\} &= \sum_{\mathbf{x}_q \in Q_T} [B_T \quad B_{\partial T}]^{\text{trans}} (\mathbf{x}_q) \cdot \{\mathbf{P}_T^k(\mathbf{G}_T^k(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n}))\} (\mathbf{x}_q) \\ &+ \beta [Z_T \quad Z_{\partial T}]^{\text{trans}} \cdot [Z_T \quad Z_{\partial T}] \cdot \begin{Bmatrix} \mathbf{u}_T^{l,m,n} \\ \mathbf{u}_{\partial T}^{k,m,n} \end{Bmatrix} \end{aligned} \quad (38)$$

where the superscript $[\cdot]^{\text{trans}}$ denotes the transpose operation, and $\{\mathbf{P}_T^k(\mathbf{G}_T^k(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n}))\}$ is the stress components vector, computed by integration of the behavior law at each quadrature point \mathbf{x}_q from the values of the displacement gradient $\mathbf{G}_T^k(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})$. The external forces vector is, as is customary with the standard finite element method, the evaluation of the given bulk and boundary loads at respective cell and face quadrature points tested against the respective cell and face shape functions, and is denoted

$$\{F_T^{ext}\} = \begin{Bmatrix} \mathbf{f}_V \\ \mathbf{t}_N \end{Bmatrix} \quad (39)$$

The tangent matrix $[K_T^{tan}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})]$ is the sum of the usual product of the displacement gradients by the tangent operator $\mathbf{A}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})$ and of an additional stabilization term such that

$$\begin{aligned} [K_T^{tan}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})] &= \sum_{\mathbf{x}_q \in Q_T} [B_T \quad B_{\partial T}]^{\text{trans}} (\mathbf{x}_q) \cdot [\mathbf{A}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})] (\mathbf{x}_q) \cdot [B_T \quad B_{\partial T}] (\mathbf{x}_q) \\ &+ \beta [Z_T \quad Z_{\partial T}]^{\text{trans}} \cdot [Z_T \quad Z_{\partial T}] \end{aligned} \quad (40)$$

where $\mathbf{A}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})$ is the derivative of the stress with respect to the displacement gradient

$$\mathbf{A}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n}) = \frac{\partial \mathbf{P}_T^k}{\partial \mathbf{G}_T^k} \quad (41)$$

Following the iterative Newton method, the algebraic system to solve at the element level consists in finding the displacement increment $(\delta \mathbf{u}_T^l, \delta \mathbf{u}_{\partial T}^k)$ that solves

$$- [K_T^{tan}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})] \cdot \begin{Bmatrix} \delta \mathbf{u}_T^l \\ \delta \mathbf{u}_{\partial T}^k \end{Bmatrix} = \{F_T^{int}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})\} - \{F_T^{ext}\} = \{R_T^{m,n}\} \quad (42)$$

In particular, since both $[B_T]$ and $[Z_T]$ are expressed in terms of cell and boundary blocks, so does the tangent matrix which can be decomposed into four coupled cell-boundary blocks with the notation

$$[K_T^{tan}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})] = \begin{bmatrix} K_{TT}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n}) & K_{T\partial T}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n}) \\ K_{\partial TT}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n}) & K_{\partial T\partial T}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n}) \end{bmatrix} \quad (43)$$

Moreover, since $\mathbf{A}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})$ is definite symmetric (and positive until an eventual loss of coercivity for *e.g.* high plastic deformations), the cell block K_{TT} is invertible and one can condensate it through a Schur complement step in order to eliminate the cell unknown, such that (42) expresses only in terms of boundary increment unknowns

$$- [K_T^{tan}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})]_{\text{cond}} \cdot \{\delta \mathbf{u}_{\partial T}^k\} = \{F_T^{int}(\mathbf{u}_T^{l,m,n}, \mathbf{u}_{\partial T}^{k,m,n})\}_{\text{cond}} - \{F_T^{ext}\}_{\text{cond}} = \{R_T^{m,n}\}_{\text{cond}} \quad (44)$$

with

$$\left[K_T^{tan} \right]_{cond} = \left[K_{\partial T \partial T} \right] - \left[K_{\partial T T} \right] \cdot \left[K_{TT} \right]^{-1} \cdot \left[K_{T \partial T} \right] \quad \text{and} \quad \left\{ R_T \right\}_{cond} = \left\{ R_{\partial T} \right\} - \left[K_{\partial T T} \right] \cdot \left[K_{TT} \right]^{-1} \cdot \left\{ R_T \right\} \quad (45)$$

The incremental cell displacement expresses linearly with the respect to the boundary one such that

$$\left\{ \delta u_T^l \right\} = \left[K_{TT} \right]^{-1} \left(- \left\{ R_T \right\} - \left[K_{T \partial T} \right] \cdot \left\{ \delta u_{\partial T}^k \right\} \right) \quad (46)$$

A schematic representation of an Newton iteration is given in Figure 3

Figure 3. Description schématique de l'algorithme de condensation statique

6.1. Résolution par équilibre de cellule

We propose an alternative to the static condensation solving algorithm, postulating an implicit relation between the increment of the cell unknowns and the increment of the faces, and consisting in solving locally a nonlinear system on the cell increment with a fixed face increment, in order to check the equilibrium of the cell with its faces at each iteration of the global problem. This new solution scheme is described in Figure 4, where we note i a Newton iteration for solving the global problem on the set of face unknowns, and j a Newton iteration for solving the local problem on the cell unknowns in an element.

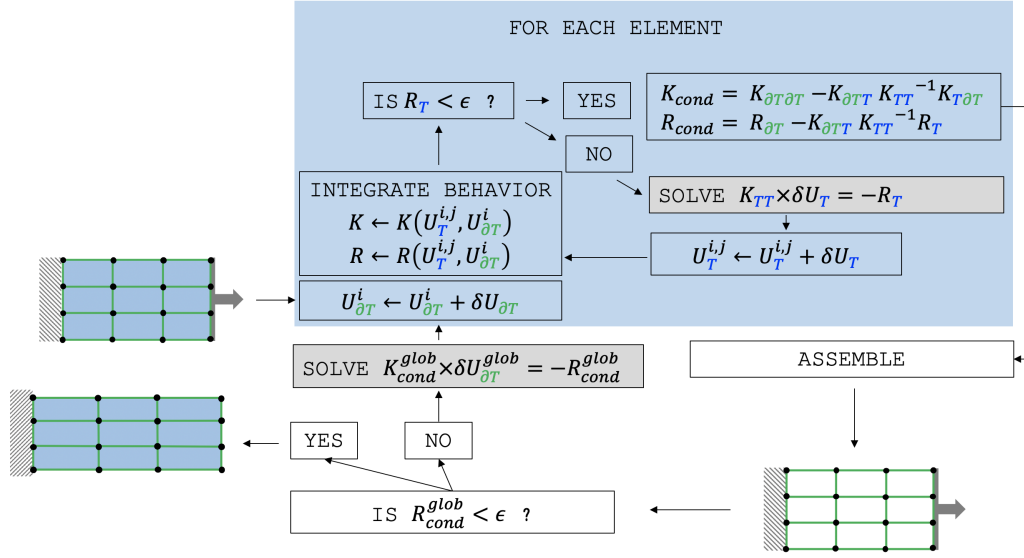

Figure 4. Description schématique de l'algorithme d'équilibre de cellule

7. Numerical examples

The goal of this section is to evaluate the proposed HHO method on benchmarks from the literature: (i) a necking of a 2D notched bar subjected to uniaxial extension, (ii) a quasi-incompressible sphere under internal pressure. We compare our results to the analytical solution whenever available or to numerical results obtained using the industrial code Cast3M. In this case, we consider a linear, respectively, quadratic, cG formulation, referred to as Q1, respectively, Q2, when full integration is used, or, Q2-RI when reduced integration is used, depending on the mesh, and a three-field mixed formulation in which the unknowns are the displacement, the pressure, and the volumetric strain fields referred to as UPG; in the UPG method, the displacement field is quadratic, whereas both the pressure and the volumetric strain fields are linear. The conforming Q1 and Q2 methods with full integration, contrary to the Q2-RI method with reduced integration in most of the situations, are known to present volumetric locking due to plastic incompressibility, whereas the UPG method is known to be robust but costly. Numerical results obtained using the UPG method are used as a reference solution whenever an analytical solution is not available. A nonlinear isotropic plasticity model with a von Mises yield criterion is used for the test cases. For the first three test cases, strain-hardening plasticity is considered with the following material parameters: Young modulus $E = 206.9$ GPa, Poisson ratio $\nu = 0.29$, hardening parameter $H = 129.2$ MPa, initial yield stress $\sigma_0 = 450$ MPa, infinite yield stress $\sigma_\infty = 715$ MPa, and saturation parameter $\delta = 16.93$. For the fourth case, perfect plasticity is considered with the following material parameters: Young modulus $E = 28.85$ MPa, Poisson ratio $\nu = 0.499$, hardening parameter $H = 0$ MPa, initial and infinite yield stresses $\sigma_\infty = 6$ MPa, and saturation parameter $\delta = 0$. In the numerical experiments reported in this section, the stabilization parameter is taken to be 1, and all the quadratures use positive weights. In particular, for the HHO method, we employ a quadrature of order $Q = 2k$ for the behavior cell integration.

7.1. Plasticity small defs

Dans le cadre de la thermodynamique des milieux continus, la combinaison de l'application des deux premiers principes de la thermodynamique donne lieu à l'équation de Clausius-Duhem qui postule la positivité de l'énergie de dissipation

$$\mathcal{D} = (\boldsymbol{\sigma}_T - \frac{\partial \psi_\Omega}{\partial \boldsymbol{\varepsilon}_T}) : \dot{\boldsymbol{\varepsilon}}_T - \rho \frac{\partial \psi_\Omega}{\partial v_{int}} \dot{v}_{int} \geq 0 \quad (47)$$

en l'absence de dépendance du problème à la température. Dans le cadre de l'hyper-élasticité qui est un processus de transformation réversible, comme évoque Section 2, l'ensemble V_{int} des variables internes v_{int} est supposé vide,

de sorte que l'inégalité (47) revient à l'équation d'égalité (??). En revanche, pour des comportements dissipatifs de nature élasto-visco-plastique, on introduit un certain nombre de variables internes, qui sont liées à l'expression de l'énergie dissipée et à l'irréversibilité de la transformation. Pour des déformations infinitésimales, on suppose la décomposition additive de la déformation

$$\underline{\varepsilon}_T = \underline{\varepsilon}_T^e + \underline{\varepsilon}_T^p \quad (48)$$

En une partie élastique $\underline{\varepsilon}_T^e$ et une partie plastique $\underline{\varepsilon}_T^p$. En particulier, dans le cadre des matériaux standards généralisés, on suppose l'existence d'un potentiel également décomposable en une partie élastique et en une partie plastique tel que

$$\psi_\Omega = \psi_\Omega^e(\underline{\varepsilon}_T^e) + \psi_\Omega^p(v_{int}) \quad (49)$$

Comme évoque Section 2, le potentiel d'énergie libre de Helmholtz ψ_Ω dépend éventuellement d'un ensemble de variables internes v_{int} dans V_{int} , qui a été supposé vide jusque là. Dans le cadre d'un comportement élasto-visco-plastique, on introduit au moins une variable interne, de manière à assurer la positivité de l'énergie dissipée. Par injection de (49) dans (47), il vient que le tenseur des contraintes $\underline{\sigma}_T$ est la la force duale associées aux déformations élastiques $\underline{\varepsilon}_T^e$. On définit également les forces thermodynamiques V_T duales des variables internes v_{int} telles que

$$\mathcal{D} = \underline{\sigma}_T : \dot{\underline{\varepsilon}}_T^p - \rho \frac{\partial \psi_\Omega}{\partial v_{int}} \dot{v}_{int} = \left\{ \underline{\sigma}_T \right\} \cdot \left\{ \dot{\underline{\varepsilon}}_T^p \right\} \geq 0 \quad \text{with} \quad V_T = -\rho \frac{\partial \psi_\Omega}{\partial v_{int}} \quad (50)$$

Par ailleurs, le cadre des matériaux standards généralisés stipule l'existence d'un convexe potential ϕ containing the origin, together with a threshold function f , that define the evolution of the generalized strains such that

$$\dot{v}_{int} = \frac{\partial \phi}{\partial f} \frac{\partial f}{\partial V_T} \quad (51)$$

Le potentiel ϕ dépend de la fonction de charge f telle que celle-ci contient l'origine, est différentiable en tout point de ...

En particulier, on introduit l'ensemble des variables internes $V_{int} = \{\underline{\varepsilon}_T^p, p\}$ avec p la déformation plastique cumulée, et le potentiel plastique

$$\psi_\Omega^p(\underline{\varepsilon}_T^p, p) = \frac{K}{2} \underline{\varepsilon}_T^p : \underline{\varepsilon}_T^p + \frac{K}{2} p^2 \quad (52)$$

où K est le module d'écrouissage cinématique, et H le module d'écrouissage isotrope. Les forces thermodynamiques associées aux variables internes $\underline{\varepsilon}_T^p$ et p sont respectivement $K \underline{\varepsilon}_T^p$ et $H p$.

$$f(\underline{\sigma}_T^p, q) = \sqrt{\frac{3}{2}} \quad (53)$$

We introduce the discrete logarithmic stress tensor $\underline{E} = 1/2 \ln(\underline{F}_T^l \cdot \underline{F}_T)$

7.2. Necking of a notched bar

In this first benchmark, we consider a 2D rectangular bar with an initial imperfection. The bar is subjected to uniaxial extension. This example has been studied previously by many authors as a necking problem 3,5,7,8,22 and can be used to test the robustness of the different methods. The bar has a length of 53.334 mm and a variable width from an initial width value of 12.826 mm at the top to a width of 12.595 mm at the center of the bar to create a geometric imperfection. A vertical displacement $u_y = 5\text{mm}$ is imposed at both ends, as shown in Figure 2A. For symmetry reasons, only one-quarter of the bar is discretized, and the mesh is composed of 400 quadrangles (see Figure 2B). The load-displacement curve is plotted in Figure 2C. We observe that, except for Q1, all the other methods give very similar results. Moreover, the equivalent plastic strain p , respectively, the trace of the Cauchy stress tensor σ , are shown in Figure 3, respectively, in Figure 4, at the quadrature points on the final configuration. A sign of locking is the presence of strong oscillations in the trace of the Cauchy stress tensor σ . We notice that the cG

formulations Q1 and Q2 lock, contrary to the HHO, Q2-RI, and UPG methods that deliver similar results. We remark, however, that the results for HHO(1;1), HHO(1;2), and Q2-RI are slightly less smooth than for HHO(2;2), HHO(2;3), and UPG. The reason is that, on a fixed mesh, the three former methods have less quadrature points than the three latter ones (see Table 1) (HHO(2;2), HHO(2;3), and UPG have the same number of quadrature points). Therefore, the stress is evaluated using less points in HHO(1;1), HHO(1;2), and Q2-RI. It is sufficient to refine the mesh or to increase the order of the quadrature by two in HHO(1;1) and HHO(1;2) to retrieve similar results to those for the three other methods (not shown for brevity).

Figure 5. ssna

Figure 6. ssna

7.3. Quasi-incompressible sphere under internal pressure

Figure 7. sphere

Figure 8. sphere

This last benchmark 6 consists of a quasi-incompressible sphere under internal pressure for which an analytical solution is known when the entire sphere has reached a plastic state. This benchmark is particularly challenging compared to the previous ones since we consider here perfect plasticity. The sphere has an inner radius $R_{in} = 0.8$ mm and an outer radius $R_{out} = 1$ mm. An internal radial pressure P is imposed. For symmetry reasons, only one-eighth of the sphere is discretized, and the mesh is composed of 1580 tetrahedra (see Figure 10A). The simulation is performed until the limit load corresponding to an internal pressure 2.54 MPa is reached. The equivalent plastic strain p is plotted for HHO(1;2) in Figure 10B, and the trace of the Cauchy stress tensor σ is compared for HHO, UPG, and T2 methods in Figure 11 at all the quadrature points on the final configuration for the limit load. We notice that the quadratic element T2 locks, whereas HHO and UPG do not present any sign of locking and produce results that are very close to the analytical solution. However, the trace of the Cauchy stress tensor σ is slightly more dispersed around the analytical solution for HHO(2;2) and HHO(2;3) than for HHO(1;1) and HHO(1;2) near the outer boundary. For this test case, we do not expect that HHO(2;2) and HHO(2;3) will deliver more accurate solutions than HHO(1;1) and HHO(1;2) since the geometry is discretized using tetrahedra with planar faces. We next investigate the influence of the quadrature order k_Q on the accuracy of the solution. The trace of the Cauchy stress tensor σ is compared for HHO(1;1), HHO(2;2), and UPG methods in Figure 12 at all the quadrature points on the final configuration for the limit load, and for a quadrature order k_Q higher than the one employed in Figure 11 (HHO(1;2) and HHO(2;3) give similar results and are not shown for brevity). We remark that, when we increase the quadrature order, UPG locks for quasi-incompressible finite deformations, whereas HHO does not lock, and the results are (only) a bit more dispersed around the analytical solution. Moreover, HHO(2;2) is less sensitive than HHO(1;1) to the choice of the quadrature order k_Q . Note that this problem is not present for HHO methods with small deformations. Furthermore, this sensitivity to the quadrature order seems to be absent for finite deformations when the elastic deformations are compressible (the plastic deformations are still incompressible). To illustrate this claim, we perform the same simulations as before but for a compressible material. The Poisson ratio is taken now as $\nu = 0.3$ (recall that we used $\nu = 0.499$ in the quasi-incompressible case), whereas the other material parameters are unchanged. Unfortunately, an analytical solution is no longer available in the compressible case. We compare again the trace of the Cauchy stress tensor σ for HHO(1;1), HHO(2;2), and UPG methods in Figure 13 at all the quadrature points on the final configuration and for different quadrature orders k_Q . We observe a quite marginal dependence on the quadrature order for HHO methods (as in the quasi-incompressible case), whereas the UPG method still locks if the order of the quadrature is increased. Moreover, in the compressible case, HHO(2;2) gives a more accurate solution than HHO(1;1).

8. Appendix

$$\begin{aligned}
 J_{I,\text{int}}^{HW} &:= \int_I \psi_I + (\nabla \mathbf{u}_I - \mathbf{G}_I) : \mathbf{P}_I \\
 &= (1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2h_T} \|\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}\|^2 + (1 - \frac{\alpha}{2}\ell) \int_{\partial K} (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \cdot \mathbf{P}_K|_{\partial K} \cdot \mathbf{n} - \int_I \mathbf{G}_I : \mathbf{P}_I
 \end{aligned} \tag{54}$$

The development of (54) is given in Appendix. Injecting (54) in (12) yields

$$\begin{aligned}
 J_T^{HW} &= \int_K \psi_\Omega + (\nabla \mathbf{u}_K - \mathbf{G}_K) : \mathbf{P}_K + (1 - \frac{\alpha}{2}\ell) \int_{\partial K} (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \cdot \mathbf{P}_K|_{\partial K} \cdot \mathbf{n} \\
 &\quad + (1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2h_T} \|\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}\|^2 - \int_I \mathbf{G}_I : \mathbf{P}_I - \int_K \mathbf{f}_V \cdot \mathbf{u}_K - \int_I \mathbf{f}_V \cdot \mathbf{u}_I - \int_{\partial_{NT}} \mathbf{t}_{\partial_{NT}} \cdot \mathbf{u}_{\partial T}
 \end{aligned} \tag{55}$$

Development 8.1 (Interface simplification). Let $C_I = \{v \in L^2(I) \mid v \cdot \mathbf{n} = \text{cste}\}$ the set of L^2 -functions which are constant along the normal axis in I . For any function in C_I , the following equality holds true:

$$\int_I v \, dV = \int_{\partial K} \int_{\epsilon=0}^{\ell} v(1 - \alpha\epsilon) \, dS \, d\epsilon = \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} v \, dS \tag{56}$$

Noticing that $\nabla \mathbf{u}_I \in C_I$, one has :

$$\begin{aligned}
 \int_I \psi_I &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{1}{2} \frac{\beta}{h_T} \nabla \mathbf{u}_I : \nabla \mathbf{u}_I \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2\ell h_T} (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \otimes \mathbf{n} : (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \otimes \mathbf{n} \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2\ell h_T} \sum_{i,j} (u_{\partial Ti} - u_{Ki}|_{\partial K})^2 n_j^2 \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2\ell h_T} \sum_j n_j^2 \sum_i (u_{\partial Ti} - u_{Ki}|_{\partial K})^2 \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2\ell h_T} \sum_i (u_{\partial Ti} - u_{Ki}|_{\partial K})^2 \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2\ell h_T} \|\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}\|^2 \\
 &= (1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2h_T} \|\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}\|^2
 \end{aligned} \tag{57}$$

Moreover, for \mathbf{P}_I in C_I :

$$\begin{aligned}
 \int_I \nabla \mathbf{u}_I : \mathbf{P}_I &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \nabla \mathbf{u}_I : \mathbf{P}_I \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{1}{\ell} (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \otimes \mathbf{n} : \mathbf{P}_K|_{\partial K} \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{1}{\ell} \sum_{i,j} (u_{\partial Ti} - u_{Ki}|_{\partial K}) n_j P_{Kij}|_{\partial K} \\
 &= \ell(1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{1}{\ell} (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \cdot \mathbf{P}_K|_{\partial K} \cdot \mathbf{n} \\
 &= (1 - \frac{\alpha}{2}\ell) \int_{\partial K} (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \cdot \mathbf{P}_K|_{\partial K} \cdot \mathbf{n}
 \end{aligned} \tag{58}$$

And Finally :

$$J_{I,int}^{HW} = (1 - \frac{\alpha}{2}\ell) \int_{\partial K} \frac{\beta}{2h_T} \|\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}\|^2 + (1 - \frac{\alpha}{2}\ell) \int_{\partial K} (\mathbf{u}_{\partial T} - \mathbf{u}_K|_{\partial K}) \cdot \underline{\mathbf{P}}_K|_{\partial K} \cdot \mathbf{n} - \int_I \underline{\mathbf{G}}_I : \underline{\mathbf{P}}_I \quad (59)$$

Development 8.2 (Elliptic projection). Let $U^h(T) \subset U(T)$ and $U^\perp(T) \subset U(T)$ such that $U(T) = U^h(T) \oplus U^\perp(T)$, and set $\mathbf{u}_T = \mathbf{u}_T^h + \mathbf{u}_T^\perp$ with $\mathbf{u}_T^h \in U^h(T)$ and $\mathbf{u}_T^\perp \in U^\perp(T)$ the orthogonal projections of \mathbf{u}_T onto $U^h(T)$ and $U^\perp(T)$ respectively. Let $V^h(\partial T) \subset V(\partial T)$ and $\mathbf{u}_{\partial T}^h \in V^h(\partial T)$ the orthogonal projection of \mathbf{u}_T onto $V^h(\partial T)$. The orthogonal projection of \mathbf{u}_T onto $U^h(\tilde{T}) = U^h(T) \times V^h(\partial T)$ is then the displacement pair $(\mathbf{u}_T^h, \mathbf{u}_{\partial T}^h)$. Let $S^h(T) = \{\underline{\boldsymbol{\tau}}_T^h \in S(T) \mid \nabla \cdot \underline{\boldsymbol{\tau}}_T^h \in U^h(T) \mid \underline{\boldsymbol{\tau}}_T^h|_{\partial T} \cdot \mathbf{n} \in V^h(\partial T)\}$, and $\underline{\mathbf{G}}_T^h \in S^h(T)$ the solution of (17) for $(\mathbf{u}_T^h, \mathbf{u}_{\partial T}^h)$ such that

$$\int_T \underline{\mathbf{G}}_T^h(\mathbf{u}_T^h, \mathbf{u}_{\partial T}^h) : \underline{\boldsymbol{\tau}}_T^h = \int_T \nabla \mathbf{u}_T^h : \underline{\boldsymbol{\tau}}_T^h + \int_{\partial T} (\mathbf{u}_{\partial T}^h - \mathbf{u}_T^h|_{\partial T}) \cdot \underline{\boldsymbol{\tau}}_T^h|_{\partial T} \cdot \mathbf{n} \quad \forall \underline{\boldsymbol{\tau}}_T^h \in S^h(T) \quad (60)$$

using the fact that $\mathbf{u}_{\partial T}^h$ is the projection of \mathbf{u}_T onto $V^h(\partial T)$ and that $\underline{\boldsymbol{\tau}}_T^h|_{\partial T} \cdot \mathbf{n} \in V^h(\partial T)$:

$$\begin{aligned} \int_T \underline{\mathbf{G}}_T^h(\mathbf{u}_T^h, \mathbf{u}_{\partial T}^h) : \underline{\boldsymbol{\tau}}_T^h &= \int_T \nabla \mathbf{u}_T^h : \underline{\boldsymbol{\tau}}_T^h + \int_{\partial T} (\mathbf{u}_T|_{\partial T} - \mathbf{u}_T^h|_{\partial T}) \cdot \underline{\boldsymbol{\tau}}_T^h|_{\partial T} \cdot \mathbf{n} & \forall \underline{\boldsymbol{\tau}}_T^h \in S^h(T) \\ &= \int_T \nabla \mathbf{u}_T^h : \underline{\boldsymbol{\tau}}_T^h + \int_{\partial T} \mathbf{u}_T^\perp|_{\partial T} \cdot \underline{\boldsymbol{\tau}}_T^h|_{\partial T} \cdot \mathbf{n} & \forall \underline{\boldsymbol{\tau}}_T^h \in S^h(T) \end{aligned} \quad (61)$$

using the divergence theorem and the fact that $\nabla \cdot \underline{\boldsymbol{\tau}}_T^h \in U^h(T)$, one has :

$$\int_T \nabla \mathbf{u}_T^\perp : \underline{\boldsymbol{\tau}}_T^h = \int_{\partial T} \mathbf{u}_T^\perp|_{\partial T} \cdot \underline{\boldsymbol{\tau}}_T^h|_{\partial T} \cdot \mathbf{n} \quad (62)$$

such that :

$$\begin{aligned} \int_T \underline{\mathbf{G}}_T^h(\mathbf{u}_T^h, \mathbf{u}_{\partial T}^h) : \underline{\boldsymbol{\tau}}_T^h &= \int_T \nabla \mathbf{u}_T^h : \underline{\boldsymbol{\tau}}_T^h + \int_T \nabla \mathbf{u}_T^\perp : \underline{\boldsymbol{\tau}}_T^h & \forall \underline{\boldsymbol{\tau}}_T^h \in S^h(T) \\ &= \int_T \nabla \mathbf{u}_T : \underline{\boldsymbol{\tau}}_T^h & \forall \underline{\boldsymbol{\tau}}_T^h \in S^h(T) \end{aligned} \quad (63)$$

which states that $\underline{\mathbf{G}}_T^h(\mathbf{u}_T^h, \mathbf{u}_{\partial T}^h)$ is the orthogonal projection of $\nabla \mathbf{u}_T$ onto $S^h(T)$.
